

IMPLEMENTATION COMPONENTS AND ARTIFACT FLOW

ACROSS THE FLOW

snapshot_inspector	pgc-inspector	reads sealed state · never writes
transformation	pgc-transformation	P0–P8 · derives the successor
conformance_workloads	pgc-workloads	makes conformance observable
business_domains	pgc-domains	the domains the snapshot binds
protocol_transport	— not packaged	boundary contracts · local only

The declarations are not shipped in any wheel.

The compiler resolves the governance surface from an anchored repository, so one surface governs a build rather than a packaged copy competing with it.

Seven governed domains · 410 protocol artifacts · one governance surface, at one pinned revision

Installing the toolchain is one of two steps; the second is pointing it at the surface that governs the build.

Repository count, published distributions and artifact totals are version-sensitive; the frozen manifest names the revision.
